Data Pre-Processing Checking For Null Values

Date	11 November 2022
Team Id	PNT2022TMID25822
Project Name	Smart Lender- Applicant Credibility Prediction for Loan Approval

• Let's find the shape of our dataset first, To find the shape of our data, df.shape method is used. To find the data type, df.info() function is used.

```
In [10]: data.info()
         <class 'pandas.core.frame.DataFrame'>
         RangeIndex: 614 entries, 0 to 613
         Data columns (total 13 columns):
                             614 non-null object
         Gender
                              601 non-null object
         Married
                             611 non-null object
                             599 non-null object
         Dependents
         Education
                              614 non-null object
         Self_Employed
                             582 non-null object
                              614 non-null int64
         ApplicantIncome
         CoapplicantIncome
                             614 non-null float64
         LoanAmount
                             592 non-null float64
         Loan_Amount_Term
                              600 non-null float64
                             564 non-null float64
         Credit_History
         Property Area
                              614 non-null object
                             614 non-null object
         dtypes: float64(4), int64(1), object(8)
         memory usage: 62.4+ KB
```

• For checking the null values, df.isnull() function is used. To sum thosenull values we use .sum() function to it. From the below image we found that there are no null values present in our dataset. So we can skip the handling of the missing values step.

```
\label{loss_power_loss} \begin{tabular}{ll} data = pd.read_csv(r"C:\Users\ELCOT\Downloads\Dataset\loan\_prediction.csv") \\ data.isnull().any() \end{tabular}
In [9]: import pandas as pd
Out[9]: Loan_ID
          Gender
          Married
                                     True
          Dependents
                                     True
          Education
                                    False
          Self_Employed
          ApplicantIncome
                                    False
          CoapplicantIncome
                                    False
          LoanAmount
                                      True
          Loan_Amount_Term
          Credit_History
                                     True
                                    False
          Property_Area
          Loan_Status
                                    False
          dtype: bool
```

From the above code of analysis, we can infer that columns such as gender, married, dependents, self-employed, loan amount, loan amounttern, and credit history are having the missing values, we need to treat them in a required way.

```
In [16]: data['Gender']-data['Gender'].fillna(data['Gender'].mode()[0])
In [11]: data['Married']-data['Married'].fillna(data['Married'].mode()[0])
In [12]: data['Dependents']-data['Dependents'].fillna(data['Dependents'].mode()[0])
In [13]: data['Self_Employed']-data['Self_Employed'].fillna(data['Self_Employed'].mode()[0])
In [14]: data['LoanAmount']-data['LoanAmount'].fillna(data['LoanAmount'].mode()[0])
In [15]: data['Loan_Amount_Term']-data['Loan_Amount_Term'].fillna(data['Loan_Amount_Term'].mode()[0])
In [17]: data['Credit_History']-data['Credit_History'].fillna(data['Credit_History'].mode()[0])
```

We will fill the missing values in numeric data type using the mean value ofthat particular column and categorical data type using the most repeated value.
